Runtime Errors

① Logical Errors (bugs)

② Exceptions

In C++ Exceptions can be handled by three key words.

try
throw
catch

try : A code which is expected to generate an exception should be enclosed in a try block. Try will indentify the exception when it is generated.

throw : throw is a part of the try block. which will throw the exception generated.

catch : catch will catch the exception and provides the solution to handle the exception.

Note : catch should be immediately after the try block

respective throw should have respective catches.
