Amzetta

30 + 30 } 1 1/2 hr

90 mins

↓

Snippets

→ wait Vs waitpid

Simultaneous

Sequential

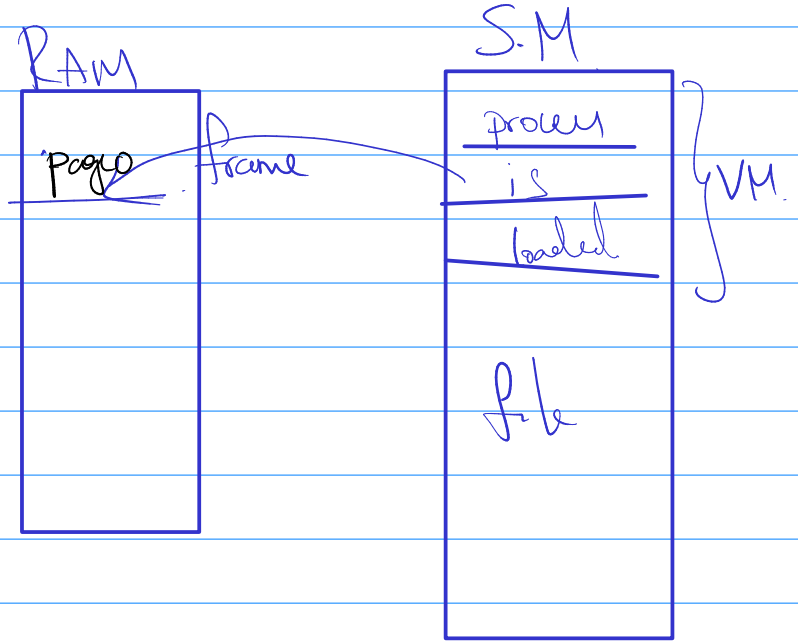

→ Scheduling algo :-

$ ./a.out

CPU ↔ Registers

↔ RAM

↔ Cache memory

frame size in RAM = page size in VM

long term scheduling
Mid term Scheduling
Shor term Scheduling

Long term Scheduling :-

↓

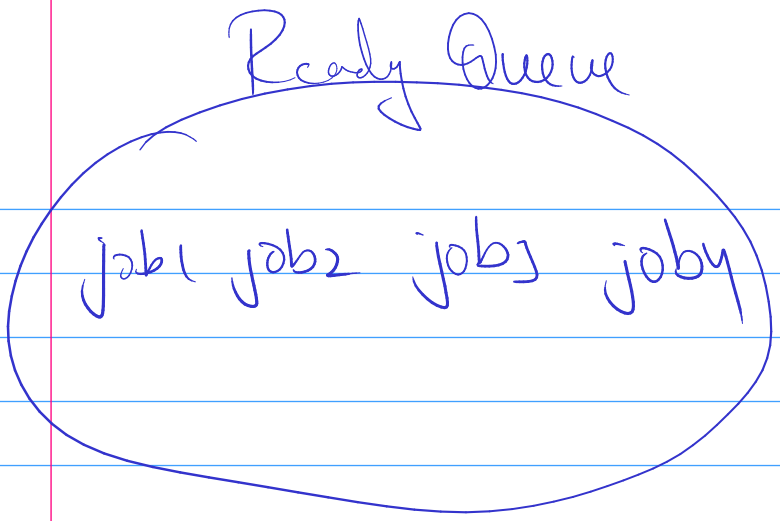

it comes into the existance only once in a process life time.

./a.out

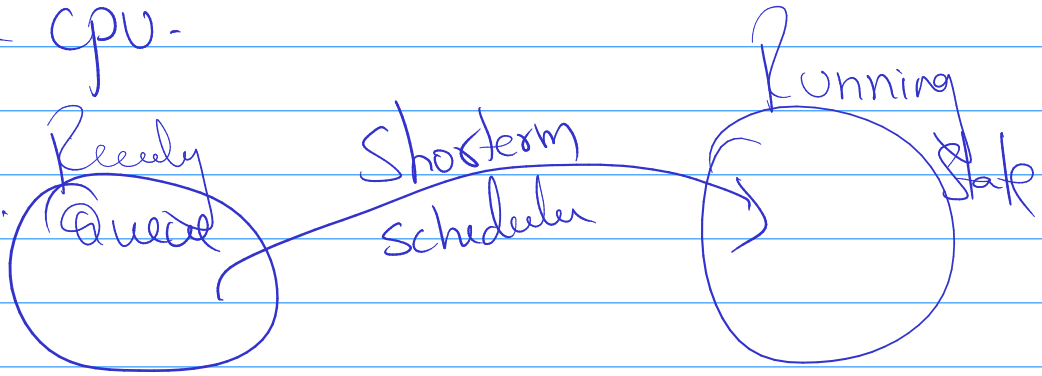

Launch

Long term Schedule :-

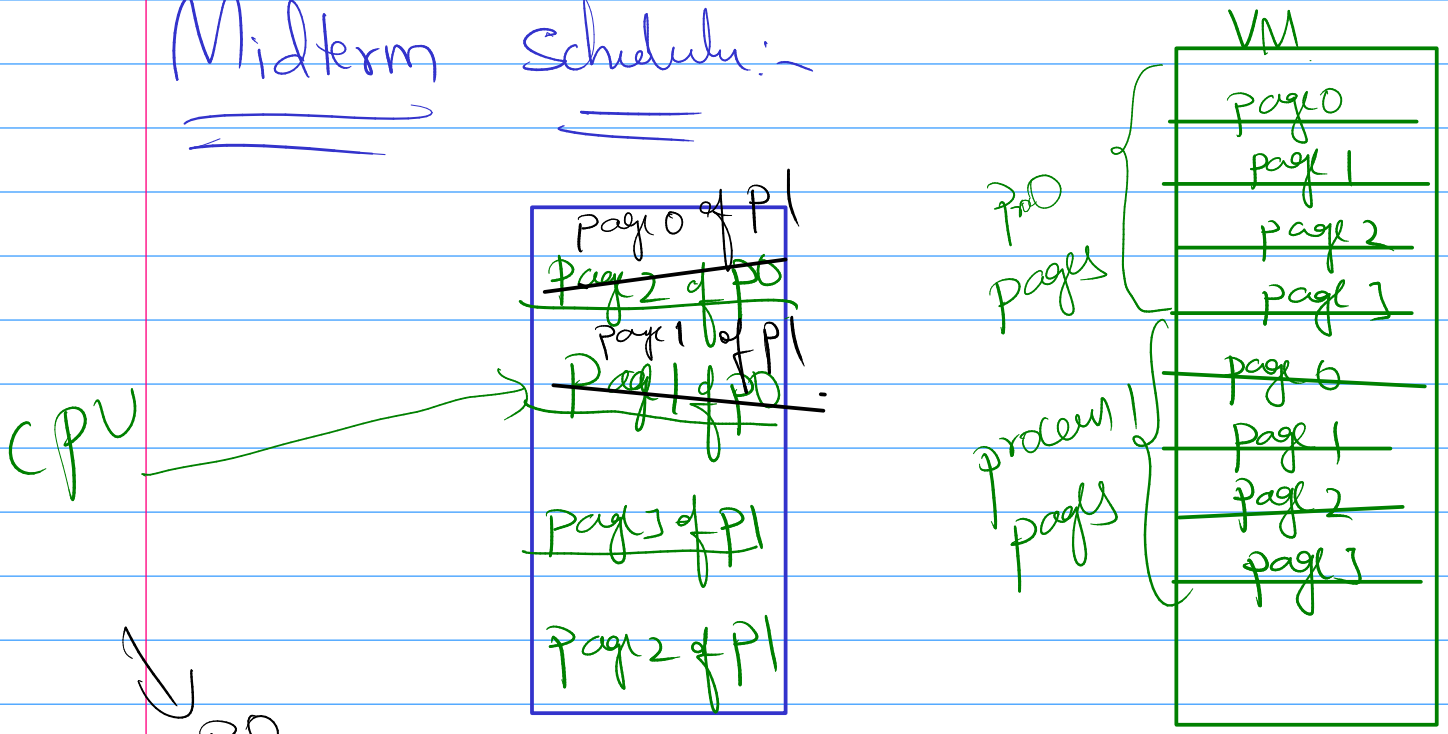

Moving a job from pool of jobs to ready Queue.

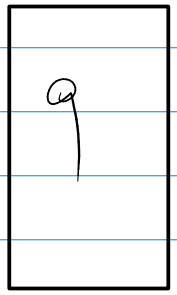

Shortterm scheduler is selecting the job from a ready Queue to give the cpu.

Midterm Scheduler:-

Midterm Scheduler brings the swapped out pages of a process when it is scheduled.

P0 → 1 sec

cpu time

P0 — P1 — P0

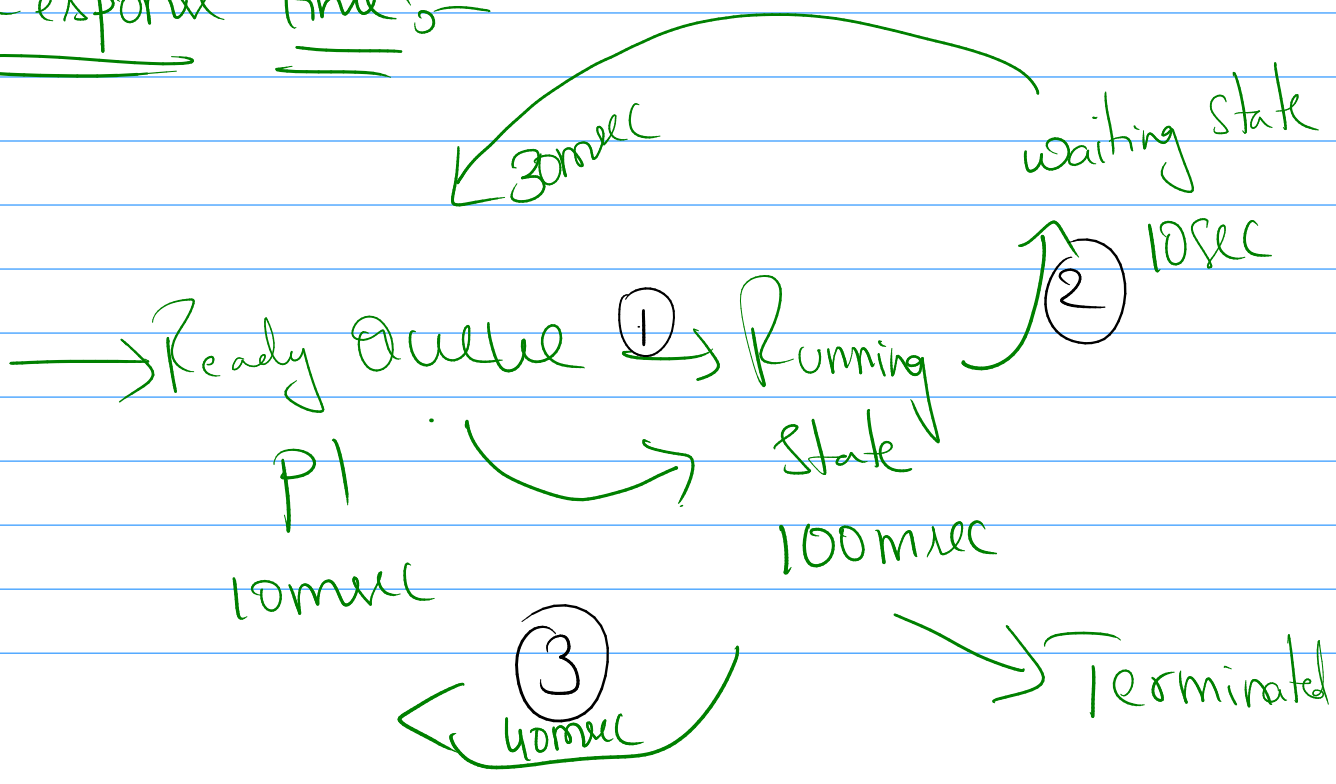

10msec

10msec

Attributes (or) performance Metrics for a cpu Scheduling algo :-

1) Response time
2) Turnaround time (process life time)
3) Throughput
4) cpu utilization
5) starvation time.
6) Fairness

Response time :-

Sum of intervals spent in ready Queue

Assign.1

20 mins

6PM

7PM

1min

9PM

19 mins

Burst time:-

The CPU time required to complete a process.

Turnaround time ≥ Burst time

Scheduling algo

This will not get effected by a Scheduling algo

fairness:-

How fairly the cpu is allocated to the processes.

CPU utilization :-

P0 → wait 10 min

Scheduling algo should P1

keep CPU busy for most of the time.

CPU Scheduling algo is efficient (best)

if it provides

1) less starvation, less Response time, less Turnaround time.

2) More throughput, More CPU utilization, high fairness.
