THREAD MANAGEMENT 2

Objective:

To understand job concurrency, mainly to create multiple therads and how they are executing , exit status , collecting exit status by main thread.

TASK:

The application when executed it should perform copy operation on files by using threads.

So, here our application should create 2 separate threads.
Each thread should perform separate task as mentioned bellow.

Thread1: Always should give status of data i.e.., how much data has been copied into the destination file and how much time left.

Thread2: Should copy the data from source file to destination file

RESTRICTIONS:

1. In **Thread2 ,** while opening the source file , if source file is not present then it should print **error message** and terminate the application.

2. In **Thread2** , destination file should open in write mode. If destination file is not present , it should create a new file.

3. In **Thread2** , for every 0.5 sec , 1 byte of data should copy into destination file.

4. In **Thread1 ,** should print some statistics on pts.

(For statistics info .., goto next page)

For Ex:

consider 60 Bytes of data copying from source to destination file.

Intially: **0% of data copied , 30 sec remaning time.**

.
.
.
.

After few sec .., (26 Bytes copied)

43.3 % of data copied , 17 sec remaning time.

.
.
.
.

After few sec ..,

100% of data copied , 0 sec remaning time.

Calculations: As per above example .,

How much data has been copied = 100/(total_size)*(no_bytes_copied).

How much time remaining = 0.5 * (total_size – no_bytes copied).
